The Story of Photonics and Single Molecules, and the Challenges and Promises of Super-Resolution Microscopy and Dynamical Tracking in Biological Imaging

William E. Moerner, Nobel Laureate 2014, *Stanford University, USA*

Roughly 30 years ago, low temperature experiments aimed at establishing the ultimate limits to optical storage in solids led to the first optical detection and spectroscopy of a single molecule in the condensed phase. At this unexplored ultimate limit, many surprises occurred where single molecules showed both spontaneous changes (blinking) and light-driven control of emission, properties that were also observed in 1997 at room temperature with single green fluorescent protein variants. In 2006, PALM and subsequent approaches showed that the optical diffraction limit of ~ 200 nm can be circumvented to achieve super-resolution fluorescence microscopy, or nanoscopy, with relatively nonperturbative visible light. Essential to this is the combination of single-molecule fluorescence imaging with active control of the emitting concentration and sequential localization of single fluorophores decorating a structure. Super-resolution microscopy has opened up a new frontier in which biological structures and behavior can be observed in live cells with resolutions down to 20-40 nm and below, and many examples abound. Current methods development research addresses ways to image in thick cells and to extract more information from each single molecule such as 3D position and orientation, as well as to assure not only precision, but also accuracy. Still, it is worth noting that in spite of all the interest in super-resolution, even in the “conventional” single-molecule tracking regime where the motions of individual biomolecules are recorded in solution or in cells rather than the shapes of extended structures, much can be learned about biological dynamical processes when ensemble averaging is removed.

W. E. (William Esco) Moerner, the Harry S. Mosher Professor of Chemistry and Professor, by courtesy, of Applied Physics at Stanford University, conducts research in physical chemistry and chemical physics of single molecules, single-molecule biophysics, super-resolution imaging and tracking in cells, and trapping of single molecules in solution. His interests span methods of precise quantitation of single-molecule properties, to strategies for three-dimensional imaging and tracking of single molecules, to applications of single-molecule measurements to understand biological processes in cells, to observations of the photodynamics of single photosynthetic proteins and enzymes. He has been elected Fellow/Member of the NAS, American Academy of Arts and Sciences, AAAS, ACS, APS, and OSA. Major awards include the Earle K. Plyler Prize for Molecular Spectroscopy, the Irving Langmuir Prize in Chemical Physics, the Pittsburgh Spectroscopy Award, the Peter Debye Award in Physical Chemistry, the Wolf Prize in Chemistry, and the 2014 Nobel Prize in Chemistry.

Controlling Light on the Nanoscale

John B. Pendry, *Imperial College London, UK*

Our intuitive understanding of light has its foundation in the ray approximation and is intimately connected with our vision: as far as our eyes are concerned light behaves like a stream of particles. Here we look inside the wavelength and study the properties of plasmonic structures with dimensions of just a few nanometres: a tenth or even a hundredth of the wavelength of visible light, where the ray picture fails utterly. In this talk we show how the new concept of transformation optics that manipulates electric and magnetic field lines rather than rays can provide an equally intuitive understanding of sub wavelength phenomena and at the same time be an exact description at the level of Maxwell's equations. The concepts are applied to a number of plasmonic structures.

Professor Sir John Pendry is a condensed matter theorist at Imperial College, London. He received his Ph.D. from the University of Cambridge in 1969 and worked at Bell Labs from 1972-1973. He has held his professorship in the Blackett Laboratory (Imperial College, London) since 1981. Shortly after, he became the head of the Physics Department and Principle (Dean) of faculty of Natural Sciences. He is currently the Chair in Theoretical Solid State Physics. Prof Pendry is a Fellow of many academic societies, including the Royal Society, the National Academy of Sciences of United States, American Academy of Arts and Sciences, the Institute of Physics (IOP), the Optical Society of America (OSA), American Physical Society (APS), etc. In 2004, he was knighted in the British Honours for his services to science.

Professor Pendry is one of the most highly cited British Scientists. He is recognized worldwide for his pioneering work on the structure of surfaces and their interaction with electrons and photons. He has also worked extensively on transport in disordered systems where he produced a complete theory of the statistics of transport in one-dimensional systems. He founded the field of “metamaterials”, a concept for engineered structures whose electromagnetic properties depend on their internal structure rather than their chemical constitution. He discovered that a perfect lens manufactured from negatively refracting material would circumvent Abbe’s diffraction limit to spatial resolution, which has stood for more than a century. His most recent innovation of transformation optics gives the metamaterial specifications required to rearrange electromagnetic field configurations at will. In its simplest form, the theory shows how we can direct field lines around a given obstacle and thus provide a cloak of invisibility. Several realizations of this concept have been built some operating at radar and others at visible wavelengths.

Conference Program

Professor Pendry has won numerous awards, including the Dirac Medal in 1996, the Royal Medal in 2006, the UNESCO-Niels Bohr gold medal in 2009, the Isaac Newton Medal in 2013, the Kavli Prize in Nanoscience in 2014, the Dan David Prize in 2016, etc.

Optical Coherence Tomography: from Healthcare Idea to Healthcare Impact

Eric A. Swanson, *Acacia Communications, USA*

The commercialization and growth of OCT which has occurred over the past 25 years has been highly impactful, scientifically, clinically, and economically. Many factors have helped drive this success starting with the clinical need for new cost-effective high-resolution minimally invasive imaging solutions for various diagnostic and therapeutic applications. But equally important to this success was the intertwined role of researchers, engineers, clinicians, professional societies, government agencies, government funding, regulatory bodies, entrepreneurs, venture capitalists, and small and large corporate entities within biomedical optics industry and other industries. This talk will review some of the history of the commercialization of OCT and illustrate how the benefits of a healthy ecosystem and the power of tight collaboration across engineering, clinical medicine, and for-profit business and healthcare organizations overcame the complex time-consuming process to close the gap between a healthcare idea and healthcare impact.

Eric Swanson is an active participant in a variety of entrepreneurial, industrial, academic, and volunteer activities. He chairs the board of directors for Acacia Communications and is a member of the boards of directors for NinePoint Medical and Curata. He serves on the governing board of the Danish National Quantum Innovation Center is an affiliate of the MIT Deshpande Center for Entrepreneurship and MIT Translational Fellows Program.

These companies have evolved over time and shipped well over \$1B in products around the world. Mr. Swanson performed research and development at Massachusetts Institute of Technology Lincoln Laboratory for 16 years. He served in several technical and managerial roles of an R&D group working on fiber optical networks, inter-satellite laser communication systems, and optical coherence tomography.

Subcellular surgery and nanosurgery

Eric Mazur, *Harvard University, USA*

We use femtosecond laser pulses to manipulate sub-cellular structures inside live and fixed cells. Using only a few nanojoules of laser pulse energy, we are able to selectively disrupt individual mitochondria in live bovine capillary epithelial cells, and cleave single actin fibers in the cell cytoskeleton network of fixed human fibroblast cells. We have also used the technique to micromanipulate the neural network of *C. Elegans*, a small nematode. Our laser scalpel can snip individual axons without causing any damage to surrounding tissue, allowing us to study the function of individual neurons with a precision that was not achievable before.

Eric Mazur is the Balkanski Professor of Physics and Applied Physics and Dean of Applied Physics at Harvard University, Member of the Faculty of Education at the Harvard Graduate School of Education, and President of the Optical Society. Meanwhile, Mazur is an internationally recognized educational innovator, and a sought-after speaker.

Eric Mazur's research group uses ultra-short laser pulses to study ultrafast dynamics in physical systems and to create extreme non-equilibrium conditions in matter. For instance, ultrashort laser pulses provide a direct view of the ultrafast carrier and lattice dynamics in photo excited solids. A better understanding of electron behavior in solids is important for both microelectronics and micromachining applications. Mazur's group also uses these short laser pulses to coherently control the lattice dynamics in solids on the femtosecond time scale.

Overcoming Hysteresis by Understanding the Formation of Interface Barriers – towards Engineering Environmentally Stable and Efficient Perovskite Cells and Modules

Christoph Josef Brabec, *University of Erlangen-Nuremberg, Germany*

Thin-film solar cells based on hybrid organo-halide lead perovskites achieved power conversion efficiency exceeding 22%. One major bottleneck allowing to drive this technology further towards commercialization are the interfacial losses at the hole and/or electron transporting contacts in state-of-art devices. We recently demonstrated that hysteresis is the direct consequence of erroneous interface design. By inserting a thin layer of fullerenes, we are able to manipulate the first monolayer of the perovskite such to reduce the charge carrier injection barrier. A detailed investigation of the interface reveals a complex mechanism allowing ionic charge compensation across the interface. In combination with engineering an advanced, low cost and dopant free top interface, we increased the efficiency of hysteresis free, regular planar solar cells, processed at low temperature close to 20 %. Combining such stacks with corrosion resistant, metal free top electrodes results in 1000's of hours light stability under inert atmosphere. Novel processing concepts to convert such efficient cell stacks into fully solution processed tandem cells or module assemblies are introduced and benchmarked vs classical vacuum based metallization.

Professor Christoph J. Brabec is holding the chair "materials for electronics and energy technology (i-MEET)" at the materials science of the Friedrich Alexander University Erlangen-Nürnberg. Further, he is the scientific director of the Erlangen division of the Bavarian research institute for renewable energy (ZAE Bayern, Erlangen), board member of the ZAE Bavaria and board member of the Energy Campus Nürnberg.
